16 Abstract

17

18 The errors and uncertainties associated with gap-filling algorithms of water, carbon and energy fluxes
19 data, have always been one of the main challenges of the global network of microclimatological tower
20 sites that use eddy covariance (EC) technique. To address these concerns, and find more efficient gap-
21 filling algorithms, we reviewed eight algorithms to estimate missing values of environmental drivers,
22 and separately, nine algorithms for the three major fluxes typically found in EC time series. We then
23 examined the algorithms' performance for different gap-filling scenarios utilising the data from five
24 EC towers during 2013. This research's objectives were a) to evaluate the impact of the gap lengths on
25 the performance of each algorithm; and b) to compare the performance of traditional and new gap-
26 filling techniques for the EC data, for fluxes and separately for their corresponding meteorological
27 drivers. The algorithms' performance was evaluated by generating nine gap windows with different
28 lengths, ranging from a day to 365 days. In each scenario, a gap period was chosen randomly, and the
29 data were removed from the dataset, accordingly. After running each scenario, a variety of statistical
30 metrics were used to evaluate the algorithms' performance. The algorithms showed different levels of
31 sensitivity to the gap lengths; The Prophet Forecast Model (FBP) revealed the most sensitivity, whilst
32 the performance of artificial neural networks (ANNs), for instance, did not vary as much by changing
33 the gap length. The algorithms' performance generally decreased with increasing the gap length, yet
34 the differences were not significant for the windows smaller than 30 days. No significant difference
35 between the algorithms were recognised for the meteorological and environmental drivers. However,
36 the linear algorithms showed slight superiority over those of machine learning (ML), except the
37 random forest algorithm (RF) estimating the ground heat flux (RMSEs of 28.91 and 33.92 for RF and

38 classic linear regression (CLR) respectively). However, for the major fluxes, ML algorithms and the
39 MDS showed superiority over the other algorithms. Even though ANNs, random forest (RF) and
40 extreme gradient boost (XGB) showed comparable performance in gap-filling of the major fluxes, RF
41 provided more consistent results with slightly less bias, as against the other ML algorithms. The results
42 indicated no single algorithm that outperforms in all situations, but the RF is a potential alternative
43 for the MDS and ANNs as regards flux gap-filling.

44

45 1. Introduction

46 To address the global challenges of climatological and ecological changes, environmental
47 scientists and policymakers are demanding data that are continuous in time and space. In addition,
48 there is a need for quantifying and reducing uncertainties in such data, including observations of
49 carbon, water and energy exchanges that are crucial components in national/international flux
50 networks and global earth observing systems. Satellites partially fill this gap as they provide excellent
51 spatial coverage but have limited temporal resolution, and not measured at a point scale. As such,
52 high-quality long-term site observations of ecosystem process and fluxes are needed that are
53 continuous in time and space. The global eddy covariance (EC) flux tower network (FLUXNET),
54 consists of its regional counterparts (i.e. AmeriFlux, EUROFLUX, OzFlux, etc.) and was established in
55 the late 1990s to address the global demand for such information (Aubinet et al., 1999; Baldocchi et al.,
56 2001; Beringer et al., 2016a; Hollinger et al., 1999; Menzer et al., 2013; Tenhunen et al., 1998). Despite
57 EC data being frequently used to validate process modelling analyses, field surveys, and remote
58 sensing assessments (Hagen et al., 2006), there are some serious concerns regarding the technique's
59 challenges, e.g. data gaps and uncertainties. Hence, filling data gaps and reducing uncertainties
60 through better gap-filling techniques are highly needed.

61 Even though the EC is a common technique to measure fluxes of carbon, water and energy,
62 there are some challenges in providing robust, high-quality continuous observations. One of the
63 challenges regarding the technique, and therefore, the flux networks, is addressing data gaps and the
64 uncertainties associated with the gap-filling process, mainly when the gap windows are long (longer
65 than 12 consecutive days, as described by Moffat et al., (2007). These gaps happen quite often for a
66 variety of reasons, such as values out of range, spike detection or manual exclusion of date and time
67 ranges, instrument or power failure, herbivores, fire, eagles nests, lightning, researchers on leave, etc.
68 (Beringer et al., 2016b). Since the EC flux towers are often located in harsh climates, their data are more
69 susceptible to adverse weather (i.e. rain conditions), and they sometimes prevent quick access to sites
70 for repair and maintenance. As a result, this issue can, in turn, produce gaps which might be relatively
71 long (Isaac et al., 2017), and thus, problematic as follows. Firstly, loss of data is considered a threat to
72 scientific studies depending on the missing data quantity, pattern, mechanism and nature (Altman
73 and Bland, 2007; Molenberghs et al., 2014; Tannenbaum, 2010). That is because using an incomplete
74 dataset might lead to biased, invalid and unreliable results (Allison, 2000; Kang, 2013; Little, 2002).
75 Second, continuous gap-filled data are required to calculate the annual or monthly budgets of carbon
76 or water balance components (Hutley et al., 2005).

77 Other than the challenges caused by missing data, there are several sources of errors and
78 uncertainties in the EC technique. Firstly, random error is associated with the stochastic nature of
79 turbulence, associated sampling errors (incomplete sampling of large eddies, uncertainty in the
80 calculated covariance between the vertical wind velocity and the scalar of interest), instrument errors,
81 and footprint variability (Aubinet et al., 2012). For instance, Dragoni et al. (2007) analysed EC-based
82 data of Morgan-Monroe State Forest for eight years (1999-2006) and assessed that instrument
83 uncertainty was equal to 3% of the total annual NEE. Another primary source of uncertainty in EC
84 measurements is systematic errors caused by methodological challenges and instrument calibration
85 problems (e.g. sonic anemometer errors, spikes, gas analyser errors, etc.). Finally, one of the sources
86 of uncertainties is data processing, especially data gap-filling (Isaac et al., 2017; Moffat et al., 2007;
87 Richardson et al., 2012; Richardson and Hollinger, 2007).

88

89 There are several uncertainties pertaining to gap-filling of missing values, including
90 measurement uncertainty (Richardson and Hollinger, 2007), lengths and timing of the gaps (Falge et
91 al., 2001; Richardson and Hollinger, 2007) and the particular gap-filling algorithm that is used (Falge
92 et al., 2001; Moffat et al., 2007). However, there are two dominant issues of long data gaps and the
93 choice of a particular gap-filling algorithm (Aubinet et al., 2012). Firstly, long gaps can significantly
94 increase the total amount of uncertainty as the ecosystem behaviour might change because of different
95 agricultural periods or phenological phases (e.g. growing season, harvest period, bushfire, etc.). And
96 thereby show different responses under similar meteorological conditions (Aubinet et al., 2012; Isaac
97 et al., 2017; Richardson and Hollinger, 2007). Consequently, the period in which a long gap happens
98 is important. For example, research undertaken by Richardson & Hollinger (2007) on data from a
99 range of FLUXNET sites revealed that a week data gap during spring green-up in a forest led to a
100 higher uncertainty over a three-week gap period during winter. Second, each gap-filling algorithm
101 has its strengths and weaknesses; for instance, Moffat et al. (2007) compared 15 different commonly-
102 used gap-filling algorithms. They found no significant difference between the performance of the
103 algorithms with “good” reliability based on analysis of variance of RMSE. Besides, the overall gap-
104 filling uncertainty was within $\pm 25 \text{ g C m}^{-2} \text{ yr}^{-1}$ for most of the proper algorithms, whereas, the other
105 algorithms generated higher uncertainties of up to $\pm 75 \text{ g C m}^{-2} \text{ yr}^{-1}$, showing that the uncertainty
106 provided by reliable methods can be considerably smaller. This result is similar to the findings of
107 Richardson & Hollinger (2007) who found that for the datasets used in their study that uncertainties
108 of up to $\pm 30 \text{ g C m}^{-2} \text{ yr}^{-1}$ were from long gaps by appropriate algorithms. Considering that the data
109 provided by EC tower networks are of use for research, government and policymakers, robust gap-
110 filling is a need to quantify and reduce uncertainties in flux estimations.

111

112 Several methods have been typically used to fill data gaps in both fluxes and their
113 meteorological drivers to manage the missing data problem. Due to computational constraints of
114 complex algorithms, early works to impute EC data gaps used interpolation methods based mostly
115 on linear regression or temporal autocorrelation (Falge et al., 2001; Lee et al., 1999). These approaches

116 were replaced quickly by more sophisticated methods such as non-linear regressions (Barr et al., 2004;
117 Falge et al., 2001; Moffat et al., 2007; Richardson et al., 2006); look-up tables (Falge et al., 2001; Law et
118 al., 2002; Zhao and Huang, 2015); artificial neural networks (ANNs) (Aubinet et al., 1999; Beringer et
119 al., 2016a; Cleverly et al., 2013; Hagen et al., 2006; Isaac et al., 2017; Kunwor et al., 2017; Moffat et al.,
120 2007; Papale and Valentini, 2003; Pilegaard et al., 2001; Staebler, 1999); mean diurnal variation (Falge
121 et al., 2001; Moffat et al., 2007; Zhao and Huang, 2015), multiple imputations (Hui et al., 2004; Moffat
122 et al., 2007), etc. Each of these methods has its pros and cons as follows: a) Interpolation methods such
123 as the Mean Diurnal Variation (MDV), do not need any drivers, yet, their accuracy is lower than other
124 approaches (Aubinet et al., 2012). Moreover, this method may provide biased results on extremely
125 clear or cloudy days (Falge et al., 2001). MDV is not recommended when a gap is longer than two
126 weeks, for it cannot consider the non-linear relations between the drivers and the flux, leading to a
127 high level of uncertainty (Falge et al., 2001). And b) The look-up table, especially its modified version,
128 Marginal Distribution Sampling (MDS), has provided performance close to ANNs, and are more
129 reliable and consistent than the other algorithms so far. Hence, MDS was chosen as one of the standard
130 gap-filling methods in EUROFLUX (Aubinet et al., 2012). Nevertheless, the performance of MDS in
131 gap-filling of extra long gaps is not well known (Kim et al., 2020). c) ANNs have commonly been used
132 to gap-fill EC fluxes since 2000 and because of their robust and consistent results are considered as a
133 standard gap-filling algorithm in several networks, e.g. ICOS, FLUXNET, OzFlux, etc. (Aubinet et al.,
134 2012; Beringer et al., 2017; Isaac et al., 2017). Despite their reliable performance, ANNs –and generally
135 all other ML algorithms- face some challenges. Over-fitting, for instance, is a big concern and can
136 happen when the number of degrees of freedom is high, while the training window is not long enough
137 respectively, or the quality of the training dataset is low. This challenge becomes acute when the gaps
138 happen while the ecosystem behaviour changes and shows different responses under similar
139 meteorological conditions. Furthermore, there is a desire to have the training windows short so that
140 the algorithm can track the ecosystem behaviour shift. Yet, this increases the risk of over-fitting
141 depending on the algorithm. In other words, the training window length should be neither too short
142 to cause over-fitting, nor too long to lead algorithms to ignore ecological condition changes. Besides,
143 long gaps are considered as one of the primary uncertainty sources of CO₂ flux in the FLUXNET
144 (Aubinet et al., 2012). As a result, studying the effects of the gap lengths, as well as the window length
145 whereby an algorithm is trained are both critical challenges associated with the environmental data
146 gap-filling.

147

148 Apart from the limitations and disadvantages of the mentioned algorithms, gap-filling of fluxes
149 (e.g. NEE) experiences some other challenges that make it necessary to find or develop new gap-filling
150 algorithms. That is because the current methods are not flexible enough to perform well in special
151 occasions or extreme values (Kunwor et al., 2017), and there is almost no room to optimise them to
152 improve their outcome (Moffat et al., 2007). Moreover, even using the best available algorithm, such
153 as ANNs, the model (gap-filling) uncertainty still accounts for a sizable proportion of the total
154 uncertainties, especially when the gaps are relatively long. Since the 2000s when MDS and ANNs were
155 chosen as the most reliable gap-filling methods for EC flux observations, many new ML and

156 optimisation algorithms have been developed and used in various scientific fields. Some of which
157 have shown superiority over ANNs, either individually or as a part of a hybrid or ensemble model,
158 e.g. (Gani et al., 2016). As a result, comparing the cutting-edge algorithms with the current standard
159 ones can show whether there is any room to improve the gap-filling process within the field.
160 According to the concerns mentioned above, this paper had two objectives. a) To find out the impact
161 of different gap lengths on the performance of each algorithm. And b) to compare the performance of
162 traditional with new gap-filling techniques, separately for fluxes and their meteorological drivers,
163 particularly soil moisture, for this has always been a challenging variable to gap-fill due to biology
164 and heterogeneity of soil parameters. To address these objectives, we utilised nine different algorithms
165 (Extreme Gradient Boost (XGB), Random Forest Algorithm (RF), Artificial Neural Networks (ANNs),
166 Marginal Distribution Sampling (MDS), Classic Linear Regression (CLR), Support Vector Regression
167 (SVR), Elastic net regularisation (ELN), Panel Data (PD) and Prophet Forecast Model (FBP)) to fill the
168 gaps of the major fluxes, and eight of them (excluding MDS) to fill the gaps of the environmental
169 drivers. We then assessed their relative performance to evaluate potentially better ways to fill EC flux
170 data. To test the approaches, we used five flux towers from the OzFlux network. To evaluate the
171 performance of these algorithms, nine scenarios for gaps were planned – from a day to a whole year -
172 and applied to the datasets, and different common performance metrics (e.g. RMSE, MBE, etc.), as
173 well as visual graphs were used.

174

175 2. Materials and methods

176

177 In order to address the first objective of this research, nine different gap lengths were
178 superimposed to the datasets, i.e. 1, 5, 10, 20, 30, 60, 90, 180 and 365 days. To address the second
179 objective, we chose nine different algorithms to fill the gaps, including a wide variety of different
180 approaches, e.g. from a simple algorithm like CLR to the cutting-edge ML algorithms, such as XGB
181 (MDS was not used to gap-fill the environmental drivers). The data used in this paper came from five
182 EC towers of the OzFlux Network, i.e. Alice Springs Mulga, Calperum, Gingin, Howard Springs and
183 Tumberumba from 2012 to 2013, with a time resolution of 30 minutes, except for Tumberumba (60
184 minutes). Additionally, data coming from three additional sources outside of the network were also
185 used as ancillary data to help the algorithms fill environmental drivers' gaps.

186 2.1. Data

187 The data used for this research came from the OzFlux, which is the regional Australian and New
188 Zealand flux tower network that aims to provide a continental-scale national research facility to
189 monitor and assess Australia's terrestrial biosphere and climate (Beringer et al., 2016a). As described
190 in Isaac et al. (2017), all OzFlux towers continuously measure and record meteorological and flux
191 variables at resolutions up to 10 Hz, and use a 30 min averaging period, with a few exceptions (data
192 are available from (<http://data.ozflux.org.au/portal>)). The network acquires additional data from the
193 Australian Bureau of Meteorology (BoM), the European Centre for Medium-Range Weather
194 Forecasting (ECMWF), and the Moderate Resolution Imaging Spectroradiometer (MODIS) on the
195 TERRA and AQUA satellites for alternative data for gap-filling flux tower datasets (Isaac et al., 2017).
196 As explained by Isaac et al. (2017), OzFlux uses the BoM automated weather station (AWS) datasets
197 to gap-fill the meteorological data, the BoM weather forecasting model (ACCESS-R) for radiation and

198 soil data from 2011 onward, and MODIS MOD13Q1 for Normalised Difference Vegetation Index
 199 (NDVI) and Enhanced Vegetation Index (EVI). Moreover, the data provided by BIOS2, a physically-
 200 based model-data integration environment for tracking Australian carbon and water (Haverd et al.,
 201 2015), were also used as another ancillary source for varieties of environmental features. Current
 202 ACCESS-R and MODIS data are available from the BoM OPeNDAP (<http://www.opendap.org/>)
 203 server and TERN-AusCover data (<http://www.auscover.org.au/>), respectively.

204
 205 The datasets used in this research came from five towers from the OzFlux Network between
 206 2012 and 2013, each representative of a different climate and land cover of Australian ecological
 207 conditions; i.e. Alice Springs Mulga: Tropical and Subtropical Desert, Calperum: steppe, Gingin:
 208 Mediterranean, Howard Springs: Tropical Savanna, Tumbarumba: Oceanic (Table 1) (Beringer et al.,
 209 2016a). The datasets included 15 meteorological drivers as well as three major fluxes recorded (Table
 210 2) based upon EC technique at a 30-minute temporal resolution, except for Tumbarumba, which was
 211 hourly. Additionally, relevant ancillary datasets for the mentioned towers were used to follow the
 212 OzFlux Network gap-filling protocol (Table 3). Each dataset was quality checked at three levels based
 213 on the OzFlux Network protocol described in (Isaac et al., 2017) and applied using PyFluxPro ver.
 214 0.9.2. To address the underestimation of canopy respiration by EC measurements at night, we used
 215 the CPD method (Barr et al., 2013) to reject nightly records when the friction velocity fell below each
 216 site's threshold value. After dismissing the inappropriate measurements, overall coverage of 72-88 %
 217 and 21-48 % were achieved for diurnal and nocturnal records during 2013 (the year to which the
 218 artificial gaps were superimposed), respectively.

219
 220 *Table 1. The information of the five towers that their data were used, including their name, location, dominant species and*
 221 *climate.*

Site	Location	Species	Climate	Latitude, Longitude (degree)
Alice Springs Mulga [AU-ASM]	Pine Hill cattle station, near Alice Springs, Northern Territory	Semi-arid mulga (Acacia aneura) ecosystem	Tropical and Subtropical Desert Climate (Bwh)	-22.2828° N, 133.2493° E
Calperum [AU-Cpr]	Calperum Station, 25 km NW of Renmark, South Australia	Recovering Mallee woodland	Steppe Climate (Bsk)	-34.0027° N, 140.5877° E
Gingin [AU-Gin]	Swan Coastal Plain 70 km north of Perth, Western Australia	Coastal heath Banksia woodland	Mediterranean Climate (Csa)	-31.3764° N, 115.7139° E
Howard Springs [AU-How]	E of Darwin, NT	Tropical savanna (wet)	Tropical Savanna Climate (Aw)	-12.4943° N, 131.1523° E
Tumbarumba [AU- Tum]	Near Tumbarumba, NSW	Wet temperate sclerophyll eucalypt	Oceanic climate (Cfb)	-35.6566° N, 148.1517° E

222
 223

224 *Table 2. List of variables and their units used in this research, including the three main fluxes and their environmental drivers.*

List of variables	Units
Drivers:	
Ah	Absolute Humidity (g m^{-3})
Fa	Available energy (W m^{-2})
Fg	Ground heat flux (W m^{-2})
Fld	Downwelling long-wave radiation (W m^{-2})
Flu	Upwelling long-wave radiation (W m^{-2})
Fn	Net radiation (W m^{-2})
Fsd	Downwelling short-wave radiation (W m^{-2})
Fsu	Upwelling short-wave radiation (W m^{-2})
ps	Surface pressure (kPa)
Sws	Soil water content (m m^{-1})
Ta	Air temperature (C)
Ts	Soil temperature (C)
Ws	Wind speed (m s^{-1})
Wd	Wind direction (deg)
Precip	Precipitation (mm)
q	Specific Humidity (kg kg^{-1})
Fluxes:	
Fc (also NEE)	CO_2 flux ($\mu\text{mol m}^{-2} \text{s}^{-1}$)
Fh (also H)	Sensible heat flux (W m^{-2})
Fe (also LE)	Latent heat flux (W m^{-2})

225
 226 The datasets whereby each environmental variable was gap-filled are shown in Table 3. For each of
 227 these variables, the same variable of the ancillary source was used to fill the gaps. For instance, to gap-
 228 fill Ah, the Ah records of AWS, ACCESS-R and BIOS2 were used. To gap-fill the missing values of
 229 fluxes, i.e. Fc (NEE), Fh (H) and Fe (LE), eight drivers were used as follows: Ta, Ws, Sws, Fg, vapour
 230 pressure deficit (VPD), Fn, q and Ts based on a combination of Random Forest (RF) feature selection
 231 and testing out a series of feature combinations. Different Python Programming Language libraries
 232 (ver. 3.6.4) were utilised for training and testing the algorithms, i.e. xgboost for XGB, fbprophet for
 233 FBP statsmodels for PD and sklearn for the rest of algorithms. Each algorithm was tuned individually
 234 using grid search, and the number of nodes, layers, irritations, etc. were chosen accordingly.

235
 236
 237 *Table 3. The ancillary sources used to gap fill each environmental driver.*

List of variables (y)	Ancillary Source
Drivers:	
Ah	AWS, ACCESS-R, BIOS2
Fa	ACCESS-R, BIOS2
Fg	ACCESS-R, BIOS2
Fld	ACCESS-R, BIOS2
Flu	ACCESS-R, BIOS2
Fn	ACCESS-R, BIOS2
Fsd	ACCESS-R, BIOS2
Fsu	ACCESS-R, BIOS2
ps	AWS, ACCESS-R
Sws	ACCESS-R, BIOS2

Ta	AWS, ACCESS-R, BIOS2
Ts	ACCESS-R, BIOS2
Ws	AWS, ACCESS-R
Wd	AWS, ACCESS-R
Precip	AWS, ACCESS-R, BIOS2

238
239

240 2.2. Gap-filling algorithms

241
242
243
244
245
246

Eight imputation algorithms for estimating 15 environmental drivers and 9 algorithms for the 3 major fluxes were chosen to make the comparison. These algorithms were selected in such a way that a variety of approaches were tested, from the standard methods like ANNs and MDS, to the newer algorithms, which have rarely or never been used in the field, such as Extreme Gradient Boosting and panel data (Table 4).

247 *Table 4. The name and the abbreviation of the gap-filling algorithms.*

Algorithm abbreviation	Full name
XGB	Extreme Gradient Boost
RF	Random Forest Algorithm
ANNs	Artificial Neural Networks
MDS	Marginal Distribution Sampling
SVR	Support Vector Regression
CLR	Classical Linear Regression
PD	Panel data
ELN	Elastic net regularisation
FBP	The Prophet Forecasting Model (Facebook Prophet)

248

249 Marginal Distribution Sampling (MDS)

250 Reichstein Reichstein et al. (2005) introduced the MDS is an enhanced look-up table method,
251 which considers both the covariation of fluxes with meteorological variables and the temporal auto-
252 correlation of the fluxes (Aubinet et al., 2012). Alongside the ANNs, the MDS is considered one of the
253 standard gap-filling methods for flux data amongst the FLUXNET, and is selected in this study to help
254 the community have a clear idea of the performance of other algorithms. Unlike the other algorithms
255 used in this research, we used Fsd, Ta and VPD as the input features for the MDS to be consistent with
256 standard application of the MDS, and for using more than three or four drivers is not generally
257 recommended (Aubinet et al., 2012). The PyFluxPro ver. 0.9.2 was used to apply the algorithm
258 (modified code used for the gaps longer than 10 days).

259

260 Artificial Neural Networks (ANNs)

261 Rooted in the 1950s, artificial neural networks are ML methods inspired by biological neural
262 networks and are classified as supervised learning methods (Dreyfus, 1990; Farley and Clark, 1954).
263 ANNs work based on several connected units called nodes, which are used to mimic a neuron's
264 functionality in an animal brain by sending and receiving signals to other nodes. The ANNs technique
265 used in this paper was the Multi-layer Perceptron regressor, which optimises the squared-loss using
266 stochastic gradient descent. Sklearn.neural_network.MLPRegressor was used to apply this method

267 in Python, and its hyperparameters were 800 and 500 for “hidden_layer_sizes” and “max_iter”,
268 respectively based on grid search. ANNs are one of the current standard approaches for gap-filling in
269 FLUXNET and in this research were picked out as a performance reference for other algorithms.

270
271 **Classical Linear Regression (CLR)**

272 A classical linear regression is an equation developed to estimate the value of the dependent
273 variable (y) based on independent values (x_i). In contrast, each x_i has its specific coefficient and an
274 overall intercept value. In this method, these coefficients are determined by minimising the squared
275 residuals (errors) of estimated vs observed values, called least squares. A CLR algorithm can be
276 formulated as follows (Freedman, 2009):

$$y = \alpha + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \dots + \beta_i X_i + \varepsilon \quad (1)$$

277 where y is the dependent variable, α is the interception, X_i s are independent variables, and β_i is
278 coefficient of X_i , and ε is the error term. We chose this algorithm as a baseline to find out how better
279 more complicated algorithms can estimate dependent variables comparatively.

280 **Random Forests (RF)**

281 Random forest, a supervised ML algorithm, used for both classification and regression,
282 consists of multiple trees constructed systematically by pseudorandomly selecting subsets of
283 components of the feature vector, that is, trees constructed in randomly chosen subspaces (Ho, 1998).
284 The RF algorithm has been developed to overcome the over-fitting problem, a commonplace
285 limitation of its preceding decision tree-based methods (Ho, 1995, 1998).
286 Sklearn.ensemble.RandomForestRegressor was used to apply this method in Python, and the
287 hyperparameters used were 5 and 1000 for “max_depth” and “n_estimators”, respectively based on
288 grid search.

289
290 **Support Vector Regression (SVR)**

291 As a non-linear method, support vector regression was developed based on Vanpik’s concept
292 of support vectors theory (Drucker et al., 1997). An SVR algorithm is trained by trying to solve the
293 following problem:

294
295 minimise $\frac{1}{2} \|w\|^2$
296 subject to $\begin{cases} y_i - \langle w, x_i \rangle - b \leq \varepsilon, \\ \langle w, x_i \rangle + b - y_i \leq \varepsilon, \end{cases}$

297 where x_i and y_i are training sample and target value in a row. The inner product plus intercept
298 $\langle w, x_i \rangle + b$ is the prediction for that sample, and ε is a free parameter that serves as a threshold.

329 sklearn.svm.SVR was used to apply this method in Python, and the hyperparameters that used were
 330 1 and 0.001 for “C” and “gamma”, respectively based on grid search.

331 **Elastic net regularisation (ELN)**

332 The elastic net is a linear regularised regression method that exerts small amounts of bias by
 333 adding two penalty components to the regressed line to decline the coefficients of independent
 334 variables and thus, provides better long-term predictions. Given that these two penalty components
 335 come from ridge regression and LASSO, the elastic net is considered as a hybrid model consists of
 336 ridge and LASSO regressions, overcoming the limitations of both. The estimates from the ELN method
 337 can be formulated as below (Zou and Hastie, 2005):

$$\hat{\beta}(elastic\ net) = \frac{(|\hat{\beta}(OLS)| - \lambda_1/2)}{1 + \lambda_2} sgn\{\hat{\beta}(OLS)\} \quad (2)$$

338 where $\hat{\beta}$ is the coefficient of each ELN independent variable, λ_1 and λ_2 are penalty coefficients of
 339 LASSO and ridge regression respectively, $\hat{\beta}(OLS)$ is the coefficient of an independent variable
 340 calculated based on ordinary least squares, and sgn stands for the sign function:
 341

$$sgn(x) = \begin{cases} 1 & x > 0 \\ 0 & x = 0 \\ -1 & x < 0 \end{cases} \quad (3)$$

342
 343 The ELN regression is good at addressing situations when the training datasets have small samples
 344 or when there are correlations between parameters. sklearn.linear_model.ElasticNet was used to
 345 apply this method in Python, and the hyperparameters used were as follows: {'alpha': 0.01,
 346 'fit_intercept': True, 'max_iter': 5000, 'normalize': False} based on grid search.

347 348 **Panel data (PD)**

349 Panel data is a multidimensional statistical method, mainly used in econometrics to analyse
 350 datasets, which involve time series of observations amongst individual cross-sections (Baltagi, 1995)
 351 usually based on ordinary least squares (OLS) or generalised least squares (GLS). A two-way panel
 352 data model consists of two extra components beyond a CLR as follows (Baltagi, 1995; Hsiao et al.,
 353 2002; Wooldridge, 2008):

$$y_{it} = \alpha + \beta X_{it} + u_{it} \quad i = 1, 2, \dots, N; \quad t = 1, 2, \dots, T \quad (4)$$

$$y_{it} = \alpha + \beta X_{it} + \mu_i + \lambda_t \quad (5)$$

354 where i and t denote the cross-section and time series dimension in a row, y is a dependent-variable
 355 vector, X is an independent variable matrix, α is a scalar, β is the coefficient of the independent-
 356 variable matrix, μ_i is the unobservable individual-specific effect, and λ_t is the unobservable time-

327 specific effect. Panel data abilities to provide a holistic analysis of different individuals, as well as
328 determining the specific impact of every single time caused its superiority over CLR. Since PD
329 requires cross-sections to be applied, we used a cross-section tower for each of the main five tower as
330 follows: Ti Tree East for Alice Springs Mulga, Whroo for Calperum, Great Western Woodlands for
331 Gingin, Daly River for Howard Springs, and Cumberland Plain for Tumbarumba. The cross-section
332 towers were chosen based on their distances (the closest ones with common years of data).

333 **Extreme Gradient Boost (XGB)**

334 Extreme gradient boost is a reinforced method of Gradient Boost introduced in 1999 that
335 works based on parallel boosted decision trees and similar to RF can be used for a variety of data
336 processing purposes including classification and regression (Friedman, 2002; Jerome H. Friedman,
337 2001; Ye et al., 2009). XGB method is resistive to over-fitting and provides a robust, portable and
338 scalable algorithm for large-scale boosting decision-trees-based techniques.
339 `sklearn.ensemble.GradientBoostingRegressor` was used to apply this method in Python, and its
340 hyperparameters were chosen based on grid search as follows: {'learning_rate': 0.001, 'max_depth': 8,
341 'reg_alpha': 0.1, 'subsample': 0.5}.

342

343 **The Prophet Forecasting Model (FBP)**

344 The Prophet Forecasting Model, also known as “prophet”, is a time series forecasting model
345 developed by Facebook to manage the common features of business time series and designed to have
346 intuitive parameters that can be adjusted without knowing the details of underlying model (Taylor
347 and Letham, 2017). A decomposable time series model was used (Harvey and Peters, 1990) to develop
348 this model, with three main components: trend, seasonality, and holidays as the equation below
349 (Taylor and Letham, 2018):

$$y(t) = g(t) + s(t) + h(t) \quad (6)$$

350

351 where $g(t)$ is the trend function, which models non-periodic changes, $s(t)$ is a function to represent
352 periodic changes, e.g. seasonality, and $h(t)$ assesses the effects of potential anomalies which occur over
353 one or more days, e.g. holidays.

354

355 *2.3. The gap scenarios*

356 In order to find out the effect of gap size on the performance of our gap-filling algorithms, the
357 data was removed randomly from nine different gap windows (i.e. 1, 5, 10, 20, 30, 60, 90, 180 and 365
358 consecutive days) during 2013. Afterwards, the data from 2012 to 2013 were used to train the
359 algorithms (excluding the superimposed gaps). Finally, the trained algorithms were used to fill the
360 artificial gaps superimposed to the datasets. The entire process permuted five times in each scenario
361 to ensure the performance was not sensitive to the gap position (i.e seasonally). As such, 15 variables,

362 9 window lengths, 8 gap-filling methods (MDS excluded), and 5 permutations across 5 towers resulted
 363 in 27,000 computations for the meteorological features. Similarly, 3 fluxes, 9 window lengths, 9 gap-
 364 filling methods, and 5 permutations across 5 towers resulted in 6,075 computations for the major
 365 fluxes, overall.

366 2.4. Statistical performance measures

367 Different statistical metrics were used to evaluate algorithms' performance and enable
 368 comparison between measured values from the flux towers with each gap-filling algorithm prediction.
 369 These metrics included the coefficient of determination (R-squared) to measure the square of the
 370 coefficient of multiple correlations (Devore, 1991), the variance of measured and modelled values (S^2)
 371 to indicate how well algorithms could follow the variations of the recorded data, the root mean square
 372 error (RMSE), the mean bias error (MBE) to capture distribution and bias of residuals, variance ratio
 373 (VR) to compare the variance of estimated values with those of measured, and the Index of Agreement
 374 (IoAd) to compare the sum of the squared error to the potential error (Bennett et al., 2013).
 375 Abbreviations and formulas of these metrics are illustrated as follows (Bennett et al., 2013):

$$R^2 = \frac{[\sum(p_i - \bar{p})(o_i - \bar{o})]^2}{\sum(p_i - \bar{p})^2 \sum(o_i - \bar{o})^2} \quad (7)$$

$$S^2 = \frac{\sum(x_i - \bar{x})^2}{N - 1} \quad (8)$$

$$RMSE = \sqrt{\frac{\sum(p_i - o_i)^2}{N - 1}} \quad (9)$$

$$MBE = \frac{\sum o_i - p_i}{N - 1} \quad (10)$$

$$VR = \frac{\sigma_p^2}{\sigma_o^2} \quad (11)$$

$$IoAd = 1 - \frac{\sum_{i=1}^n (o_i - p_i)^2}{\sum_{i=1}^n (|p_i - \bar{o}| + |o_i - \bar{o}|)^2} \quad (12)$$

382 where o_i and p_i are individual measured and predicted values respectively, \bar{o} and \bar{p} are the means of
 383 o and p , and σ^2 is the variance. S^2 is calculated separately for the observed and predicted values with
 384 the respective values defined as x representing every observed or predicted value. All of these metrics
 385 were calculated for each of the gap scenarios, and then the results of five permutations were
 386

387 concatenated. Afterwards, the metrics were calculated to avoid Simpson’s paradox or any relevant
 388 averaging issue as described by Kock and Gaskins (2016).

389 3. Results

390

391 3.1. Fluxes

392 3.1.1 CO₂ flux (Fc)

393 Even though factors such as ground heat flux (Fg) and net radiation (Fn) are fluxes, we dealt
 394 with them as environmental drivers since they drive the three major turbulent fluxes. The metrics
 395 used to evaluate the algorithms' performance (RMSE, R², MBE, IoAd and VR) (Table 5) illustrated that
 396 overall, the performance of these algorithms, particularly the ML ones, was similar, closely followed
 397 by the MDS. The XGB provided the lowest values of RMSE and one of the highest R², while the FBP
 398 and ELN had the lowest and highest values of R² and RMSE, respectively. The algorithms, however,
 399 showed different levels of sensitivity to the gap lengths, e.g. the CLR and PD showed smaller
 400 sensitivity, while the FBP showed the most sensitivity (Figure 1).

401 *Table 5. The average amounts of performance metrics for each gap-filling algorithm regarding Fc, which includes all window*
 402 *lengths and sites, ranked by RMSE using the Tukey’s HSD test at the level of 5 per cent.*

Algorithm	Mean RMSE	Mean R ²	Mean MBE	Mean IoAd	Mean VR
XGB	3.07 ^a	0.59	-0.43	0.90	0.66
RF	3.12 ^a	0.58	-0.37	0.91	0.71
ANNs	3.13 ^a	0.56	-0.33	0.90	0.69
SVR	3.34 ^b	0.47	-0.32	0.86	0.75
MDS	3.35 ^b	0.51	-0.41	0.85	0.70
PD	3.41 ^{b,c}	0.48	-0.35	0.81	0.54
CLR	3.44 ^{b,c}	0.49	-0.36	0.81	0.55
ELN	4.52 ^c	0.43	-0.37	0.73	0.39
FBP	4.15 ^d	0.47	-0.06	0.77	0.68

403

404 These outcomes were expected for the XGB as it uses a more regularised model formalisation to
 405 control over-fitting (Chen and Guestrin, 2016) which, on paper, leads to better performance as against
 406 its ML rivals. The relatively poor performance of FBP was also foreseen for unlike other algorithms,
 407 FBP did not use any feature to estimate flux values, other than the previous time series of flux values.
 408 However, the weaker performance of the ELN compared to CLR was unforeseen as by adding two
 409 penalty components to the regression line, the ELN is supposed to improve the long-term prediction
 410 compared to the traditional linear regression methods. Tukey’s HSD (honestly significant difference)
 411 test at the level of five per cent was applied to the results to determine whether the difference amongst
 412 the algorithms was significant (Table 5). Where the null hypothesis was there is no significant
 413 difference between the mean values of the RMSE. According to the results, there were significant
 414 differences between certain algorithms, and the XGB, RF and ANNs were different from the rest,
 415 showing that these three performed considerably better. Tukey’s HSD test, however, did not reject the
 416 second error probability between RF, XGB and ANNs meaning that the three algorithms were not
 417 significantly different from each other. This result agrees with the results of Falge et al. (2001) and

418 Moffat et al. (2007) in the sense that ANNs are one of the best available gap-filling algorithms, and
 419 there is no significant difference amongst the appropriate algorithms. However, the test showed that
 420 the performance of the MDS was significantly different from the ANNs. It seems that the difference
 421 has occurred because of the longer gaps (> 10 days) that had been absent from the previous studies.
 422 Finally, it is worth mentioning that Tukey's HSD is well known as a conservative test. That being said,
 423 despite no meaningful difference based on Tukey's HSD, XGB and RF might have performed better
 424 than ANNs, as the superiority of RF in gap-filling of methane flux over the ANNs, SVR, and MDS has
 425 recently been claimed by Kim et al. (2020).

426
 427 *Figure 1. A heat map of mean RMSE values of Fc across all sites based on 9 algorithms and 9 window lengths in 2013.*

428

429 To address this paper's first objective, which was to find out the sensitivity of the gap-filling
430 algorithms to the gap window length, we used the averaged RMSE, R² and MBE for each gap size
431 using the output of all algorithms for all sites (Table 6). The outcome illustrates that the longer the
432 window length got, the larger the RMSE became. Yet, no such pattern was recognisable for the R² and
433 MBE. As a result, generally, any consecutive gaps longer than 30 days seem to decline the algorithms'
434 performance noticeably. A reason for this may be that longer windows do not let the algorithms
435 accommodate seasonal changes and, therefore, different canopy physiological behaviour.

436 *Table 6. The average RMSE, R², and MBE for Fc gap-filling based on the window length including the outcome of all sites; the*
437 *differences of RMSE values were tested using the Tukey's HSD test at the level of 5 per cent.*

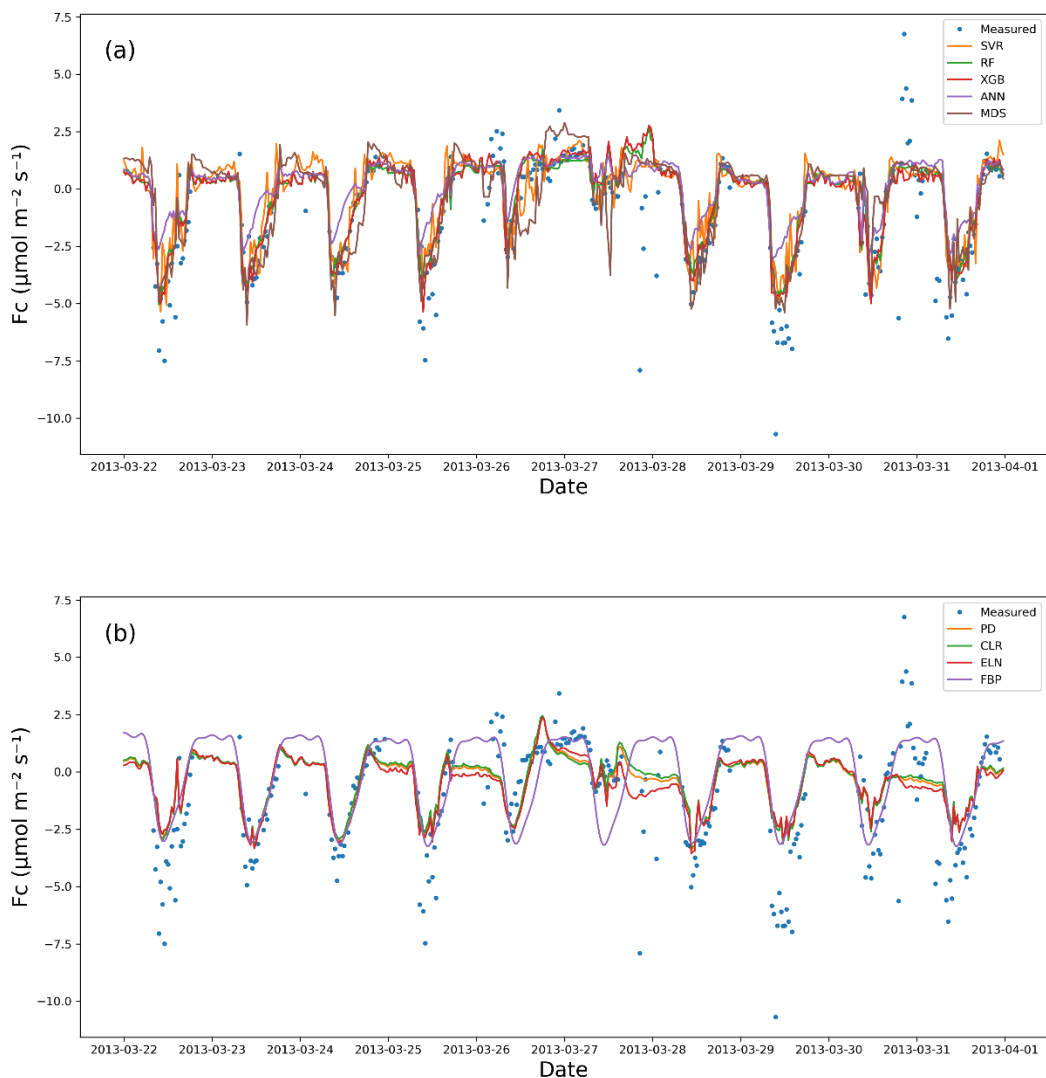

Window length	Mean RMSE	Mean R ²	Mean MBE
1-day	3.23 ^a	0.53	-0.27
5-days	3.25 ^a	0.52	-0.31
10-days	3.26 ^a	0.51	-0.29
20-days	3.27 ^a	0.51	-0.31
30-days	3.29 ^a	0.51	-0.31
60-days	3.32 ^a	0.49	-0.35
90-days	3.37 ^a	0.51	-0.38
180-days	3.43 ^a	0.50	-0.41
365-days	3.49 ^a	0.49	-0.37

438

439 According to the MBE values (Table 5), mainly, all algorithms had negative MBE indicating an
440 overestimation of the Fc values. This bias varied from tower to tower and depended on the window
441 lengths. For instance, the MBE's absolute values were larger in Gingin and Tumbarumba, while
442 considerably smaller (closer to zero) at Alice Springs Mulga and Calperum (Supplementary). The
443 lower leaf area index of the two later sites, and thus their smaller amounts of photosynthesis are likely
444 to be the reason for this. FBP, nonetheless, provided substantially lower mean bias (-0.06) compared
445 to the other algorithms, which varied between -0.32 and -0.43.

446 Observations from the EC technique often include extremely low or high values after QC,
447 especially at night, when some of the theoretical assumptions might be violated. One of the practical
448 challenges associated with the EC technique is that it is often difficult to distinguish between the good
449 data and the noise (Aubinet et al., 2012; Burba and Anderson, 2010). This problem seems to affect the
450 outcomes of the gap-filling algorithms in this research, as none of them performed ideally in capturing
451 the observed variance (Table 5 **Error! Reference source not found.**). Even though RMSE, R² and IoAd
452 showed the superiority of the XGB, RF and ANNs, the variance ratio between the estimated and
453 measured values revealed different information (Table 5), which is recognisable in Figure 2. The
454 variance ratios (VR) showed that SVR captured the extreme values of Fc better than the other
455 algorithms, 0.75 on average. The other ML algorithms –plus the MDS- though, performed closely with

456 regard to capturing the extremes that matches both the expectations, and the performance metrics
457 (Table 5).

458
459 *Figure 2. Measured vs estimated values of F_c for Calperum based on a 10-day gap window (March 22 - March 31, 2013): (a) the*
460 *ML algorithm plus the MDS, and (b) the linear models plus FBP.*

461 The linear algorithms, CLR, PD, and ELN, performed worse concerning the VR compared to the ML
462 algorithms with the VR of F_c for Calperum (Figure 2Error! Reference source not found.) confirming
463 this. Based on the figure, as expected, the ELN performed the worst in capturing the fluctuations in
464 F_c (VR = 0.39), while the performance of the other algorithms, apart from the top five, was not
465 significantly better the exception of FBP. It is noteworthy that CLR, PD, and ELN frequently predicted
466 nocturnal photosynthesis. Overall, the results showed a significant difference between the top five
467 algorithms (XGB, RF, ANNs, SVR, and MDS) and remaining algorithms, particularly in capturing the

468 fluctuations and the min-max range of Fc. However, a comprehensive comparison shows a slight
 469 superiority of the XGB and RF.

470 *3.1.2 Latent heat flux (Fe)*

471 The performance of algorithms for Fe was similar to that for Fc with respect to RMSE, MBE
 472 and R², as shown in Table 7. This similarity was not surprising since these processes are partially
 473 coupled via stomatal conductance (Scanlon and Kustas, 2010; Scanlon and Sahu, 2008). Again, the top
 474 three ML algorithms performed better, with XGB and RF being statistically significant as shown by
 475 the Tukey’s HSD (Table 7). The null hypothesis was not rejected while comparing FBP and SVR,
 476 whereas the better performance of the other algorithms was confirmed. As a result, the FBP and SVR
 477 provided the most unsatisfactory results in estimating Fe, according to the average values of the
 478 RMSE. No significant improvement in RMSE occurred when the gap lengths became shorter than 60
 479 days, meaning that the algorithms' performance did not vary considerably from a 30-day to a one-day
 480 window, especially for the top algorithms (XGB, RF, and ANNs). CLR and PD results were very
 481 similar to those for Fc, showed lower RMSE and higher R² values as against ELN, but the ELN led to
 482 a slightly lower MBE. The MBE values also showed moderately high values for the SVR, meaning that
 483 there was an absolute bias in its outcome, which might be related to overfitting. The source of the bias
 484 shown by the SVR algorithm (Figure 3), was because it could not capture the minimum values
 485 appropriately, resulting in a considerable overestimation. A common issue in estimating Fe values,
 486 which had affected all algorithms other than the FBP, was the inability to capture the negative values.
 487 In contrast to Fc results, the ANNs did not perform as well as the XGB and RF, which could be due to
 488 not capturing the maximum values compared to its rivals.

489 *Table 7. The average metrics for Fe gap-filling based on the algorithms, ranked by RMSE using the Tukey’s HSD test at the level*
 490 *of 5 per cent.*

Algorithm (Fe)	Mean RMSE	Mean R ²	Mean MBE
XGB	34.95 ^a	0.74	-3.48
RF	35.63 ^a	0.74	-3.33
ANNs	37.77 ^{a,b}	0.67	-3.94
MDS	41.74 ^{b,c}	0.64	-3.27
PD	43.28 ^{b,c}	0.64	-6.35
CLR	43.51 ^c	0.64	-6.66
Eln	44.34 ^c	0.59	-5.13
SVR	46.63 ^{c,d}	0.59	-20.45
FBP	50.53 ^d	0.52	3.01

491

492

493

494 *Figure 3. Measured vs estimated values of Fe for Calperum based on a 10-day gap window (March 22 - March 31 2013).*

495 *3.1.3 Sensible heat flux (Fh)*

496 As with the other flux results, the metrics of RMSE, R^2 and MBE showed slight superiority for
 497 XGB and RF, as well as the inferiority of the SVR and FBP over the other algorithms (Table 8).
 498 Likewise, the SVR provided relatively large negative values of MBE, showing considerable
 499 overestimation. The Tukey's HSD test of the average RMSE values confirmed that the performance of
 500 the FBP was significantly different from the rest at the level of 5 per cent, making FBP the weakest
 501 performer for Fh. On the other hand, although there was no significant difference amongst the XGB,
 502 RF and ANNs, the first two were considerably superior over the other algorithms as regards the
 503 Tukey's HSD test. Similarly to Fe, estimated values of Fh using SVR had a negative bias (Figure 4)
 504 because it was not able to provide appropriate estimations of Fh minimum values. In contrast, the
 505 ANNs performed the best in capturing the minimum values, while the other top algorithms
 506 performed almost equally well. Despite the close performance in capturing the minimum values,
 507 ANNs and MDS did not perform as well as XGB and RF in capturing the overall values, resulting in
 508 an higher RMSE. Finally, like the other fluxes, the PD performed slightly better than the CLR and
 509 ELN.

510 *Table 8. The average metrics for Fh gap-filling based on the algorithms, ranked by RMSE using the Tukey's HSD test at the level*
 511 *of 5 per cent.*

Algorithm (Fh)	Mean RMSE	Mean R^2	Mean MBE
XGB	37.23 ^a	0.92	-0.21
RF	37.55 ^a	0.91	-0.09
ANNs	40.13 ^{ab}	0.90	-0.08
MDS	43.30 ^{bc}	0.88	-9.51
SVR	43.80 ^{bc}	0.88	0.35
PD	44.96 ^c	0.88	1.36
CLR	45.03 ^c	0.88	1.64
ElN	45.19 ^c	0.87	2.16
FBP	72.91 ^d	0.73	1.07

512

514

515 *3.2. Meteorological and Environmental Drivers*

516 Since meteorological and environmental drivers are needed to fill the gaps of the three
 517 turbulent fluxes (F_c , F_e and F_h), the eight algorithms (excluding the MDS) were used to fill these
 518 drivers' gaps. The metrics of R^2 , RMSE, and MBE were calculated for all five towers and nine window
 519 lengths (16 meteorological and environmental drivers). Overall, for most meteorological drivers, the
 520 linear algorithms, especially the CLR and PD, performed slightly better than the ML algorithms such
 521 as the XGB, RF, ANNs and SVR, except for A_h , F_g and F_n . This unexpected superiority can be
 522 explained based on the two following reasons. Firstly, unlike the fluxes, the input and output features
 523 were the same here, e.g. T_a for T_a , which led to solid correlations (e.g. up to 0.99 for atmospheric
 524 pressure - p_s) as well as strong linear relationships between the independent and dependent features.
 525 These strong correlations helped the linear algorithms perform well and reduced ML algorithms'
 526 ability to capture non-linear behaviour of complicated problems. Second, ML algorithms' slight
 527 inferiority could be due to data noise where simple linear algorithms such as the CLR are usually
 528 relatively less sensitive to the noise. Therefore, over-fitting is not an issue for them when the number
 529 of observations is big enough (i.e. at least 10 to 20 observations per parameter (Harrell, 2014)). The
 530 exceptions were A_h , F_n and F_g , for which values were estimated more accurately by the XGB, ANNs
 531 and RF, especially F_g where the RMSE of RF and CLR for F_g was 28.91 versus 33.92 respectively).
 532 Tukey's HSD test for the mean RMSE values of F_g confirmed that the XGB, ANNs and RF significantly
 533 better results, while, like all other fluxes and drivers, the FBP was the worst algorithm (Table 9). Yet,
 534 according to the same test for the other drivers, there was no significant difference between the
 535 algorithms, other than the FBP, which provided the most significant mean values of the RMSE (results
 536 not shown). Importantly, though, none of the algorithms offered adequate estimations for soil
 537 moisture (S_{ws}), particularly in drier regions. This weak performance happened because S_{ws} changes
 538 dramatically during rainfall in a pulsed manner often from zero to saturation in short space of time,

539 whereas, the algorithms had been trained based on the datasets mostly reflecting non-rainy periods.
 540 These datasets, consequently, could not fit the algorithms in a way that they could estimate Sws
 541 accurately when precipitation occurs and the soil moisture increases dramatically. For instance, in a
 542 wet region like Tumbarumba, where the soil faces rainy days frequently, the time series are much less
 543 spikey. Thus, the overall performance was better in these regions than the drier ones (e.g. R^2 of 0.45
 544 and 0.26 on average for Tumbarumba and Calperum, respectively). In addition, the dataset used to
 545 gap-fill the soil moisture was a model derivation from gridded data or regional reanalysis and
 546 therefore, may not close to reality. Another challenge of estimating soil moisture comes from the low
 547 spatial coherence of soil moisture is that it can be extremely different just a couple of hundred metres
 548 away, due to storms, topography, soil structure heterogeneity, etc. (Reichle et al., 2004; Sahoo et al.,
 549 2008).

550

551 *Table 9. The average amounts of RMSE for Fg gap-filling based on the algorithms, using the Tukey's HSD test at the level of 5*
 552 *per cent.*

Algorithm (Fg)	Mean RMSE
RF ^a	28.91
XGB ^{a,b}	29.19
ANNs ^{b,c}	29.58
SVR ^c	31.46
CLR ^d	33.92
PD ^d	33.93
ELN ^d	34.09
FBP ^e	39.10

553

554 4. Discussion

555

556

557 Nine gap-filling algorithms were used in this study: Extreme Gradient Boost as XGB, Random
 558 Forest Algorithm as RF, Artificial Neural Networks as ANNs, Marginal Distribution Sampling as
 559 MDS, Support Vector Regression as SVR, Classical Linear Regression as CLR, panel data as PD, Elastic
 560 net regularisation as ELN, and The Prophet Forecasting Model as FBP. All algorithms performed
 561 similarly in estimating the meteorological and environmental drivers (turbulent fluxes included)
 562 across all stations, except the FBP, which performed poorly for it did not use any ancillary data. The
 563 best results were achieved for the 30-day gaps and shorter, while the worst results obtained for the
 564 most extended windows, 180 and 365 days. Although most of the algorithms performed almost
 565 equally well in estimating meteorological and environmental drivers, the linear algorithms (CLR, ELN
 566 and PD) performed slightly better, though not significantly using Tukey's HSD test. The only apparent
 567 exception was Fg, for which the RF provided more accurate and robust estimations. The ML
 568 algorithms and MDS, on the other hand, showed their superiority over the linear algorithms while
 569 estimating the main fluxes, Fc, Fe and Fh. For Fc, the XGB, RF and ANNs performed significantly

570 better than the FBP and all linear algorithms (i.e. the CLR, PD and ELN, yet, followed closely by the
571 SVR and MDS). The superiority of the ML algorithms and their intimate performance agreed with the
572 results of previous researchers (Falge et al., 2001; Moffat et al., 2007), who showed the superiority of
573 non-linear algorithms and no significant difference amongst the top algorithms in estimating Fc.
574 Besides, the slight superiorities of XGB and RF over ANNs, our results confirm that RF performs better
575 for EC flux gap-filling, as noted by Kim et al. (2020) for methane.

576 The XGB was the most novel ML algorithm used in this research and based on the most
577 performance metrics provided comparatively robust results in estimating the fluxes. In estimating the
578 meteorological drivers though, the XGB did not show any superiority over the other algorithms,
579 especially the linear ones. Moreover, the XGB needed four to six times longer time to be trained and
580 tuned, making it a less feasible algorithm when time or the processing power are important factors or
581 several years of data are needed to be gap-filled. Hence, we do not recommend the XGB as an
582 alternative to the current standard algorithms. Nevertheless, because of its local superiorities, this
583 algorithm might be suitable to use in an ensemble model alongside the algorithms with different
584 weaknesses.

585 The RF was the best all-around algorithm amongst the nine algorithms used in this study,
586 providing the best consistent and robust estimates of the fluxes (similar to XGB) but also being less
587 complicated and performing faster than the XGB. The RF also provided the best results for Fg, where
588 the linear algorithms did not perform well. This superiority of RF over ANNs, MDS, and SVR has
589 been shown previously by Kim et al. (2020) for gap-filling of methane, showing that it is worth testing
590 the RF for other towers, and fluxes across the FLUXNET.

591 The ANNs estimated the fluxes better than the linear algorithms, notably for Fc, yet not as
592 robust as the XGB and RF in general. For Fc and Fh, the ANNs provided bias, mainly due to
593 overestimating minimum values when the window lengths were longer than 30 days. However, since
594 the superiority of the XGB and RF was not considerable, it is difficult at this point to suggest using
595 XGB or RF as better alternatives. That is because the utility of ANNs have been validated for a long
596 time in different locations and considered as one of the most reliable algorithms in the field for more
597 than a decade (Aubinet et al., 2012; Hagen et al., 2006; Kunwor et al., 2017; Moffat et al., 2007). In other
598 words, the superiority of RF, should be assessed in several future studies to convince the network to
599 suggest RF instead of ANNs, or identify it as another standard gap-filling method. Furthermore, there
600 are a wide variety of different ANNs algorithms used in the field (Beringer et al., 2016b; Hagen et al.,
601 2006; Isaac et al., 2017; Kunwor et al., 2017; Moffat et al., 2007), and the minor superiority of RF and
602 XGB cannot be generalised without additional case studies. As such, we suggest other researchers to
603 use the RF, especially for Fh and Fc alongside the ANNs to find out which one performs better in the
604 challenging scenarios (e.g. when the gaps are long). Another option is to develop ensemble models to
605 improve the results over a single algorithm (Moffat et al., 2007). Ideally, a model with a higher level
606 of flexibility is required in the field (Hagen et al., 2006; Kunwor et al., 2017; Richardson and Hollinger,
607 2007). Finally, the ANNs, like the other ML algorithms, did not show a consistent superiority over the
608 linear algorithms regarding the environmental drivers. Therefore, we do not recommend using ML
609 algorithms in such scenarios, except for Fg, for which RF seems to be a better option.

610 The MDS performed close to, yet not as well as the XGB, RF, and ANNS in gap-filling the fluxes.
611 Its performance was close to the SVR, but was more reliable for Fe and Fh. It is worth mentioning that
612 this performance was achieved despite the MDS using fewer input features. Its performance, however,
613 was comparable with the ML algorithms, particularly when the gap lengths were relatively shorter
614 (equal to or smaller than 10 days). As such, we recommend using the MDS when the gaps are not long
615 or the available input features are limited, especially considering that the MDS performs significantly
616 faster than the ML algorithms, and is easier to use.

617 The SVR showed consistent inferiority over the other ML algorithms and did not fulfill our
618 expectations, neither for the meteorological drivers nor for the major fluxes. The only strength of the
619 SVR was that it captured the extreme values better than any other algorithm. However, because of
620 the larger RMSE the mentioned advantage seems to be achieved suspiciously and might have
621 occurred due to over-fitting. This dubious performance shows the SVR is perhaps more vulnerable to
622 the over-fitting issues regarding these data types. Hence, we suggest the SVR not to be used in
623 environmental modelling related to the reviewed drivers and fluxes, whatsoever.

624 The CLR, the simplest algorithm used in this research, provided a comparatively acceptable
625 performance in estimating the meteorological drivers, except for Fg. This algorithm, however, did not
626 perform well in assessing the fluxes, especially Fc, mainly because of its inability to capture the
627 extreme values caused by the non-linear nature of Fc to its drivers. Overall, considering the CLR
628 simplicity, resource-saving and robust performance for drivers, this algorithm seems to be the most
629 suitable way to fill the gaps of meteorological parameters in similar scenarios, where the same
630 ancillary dataset are available.

631 The PD performed slightly better than the CLR, yet it did not show a significant superiority over
632 the other linear algorithms used in the research. This unforeseen weak performance can be explained
633 due to a couple of reasons. First, one of the assumptions of using the PD is that the cross-sections'
634 behaviour (here towers) is similarly under the similar conditions (the independent variables), and the
635 only thing leads to the difference is the specific characteristics of each individual cross-section.
636 Contrariwise, it seems that the five towers selected in this research violated this assumption due to
637 them being in widely different ecosystems. Based on the previous studies in which the PD performed
638 well (Izady et al., 2013, 2016; Mahabbati et al., 2017), it appears that a decent level of homogeneity is
639 vital for the PD to perform satisfactorily. As in all previous cases, the cross-sections ecosystem had
640 significant similarities, and the distance between them was smaller. Therefore, the characteristics of
641 cross-sections, such as radiation, climate, rainfall, etc. had considerably more remarkable similarity
642 and homogeneity compared with the towers used in this research. Finally, it is worth mentioning that
643 PD has been commonly used to analyse the time series with a time resolution of weekly or longer,
644 with some exceptions using daily time steps. In this research, the data resolution was half-hourly
645 instead, which dramatically increased the computational demands of the algorithm, led to days of
646 processing for a single run. This demand happened because the algorithm creates a dummy variable
647 for each time step and the relevant matrix of variables becomes too large to compute by a regular PC.
648 Considering the computational expense of this algorithm, we recommend other researches not to use
649 PD when the time resolution is shorter than daily. Despite the limitation, we still encourage further

650 use of PD whenever there is a decent homogeneity level amongst the cross-sections and the time
651 resolution is daily or longer.

652 As a hybrid linear model, the ELN did not show any superiority over the CLR, despite its
653 modifications to provide more accurate estimations. Even though ELN performed well in estimating
654 the drivers with slight supremacy on some occasions (e.g. Fld, the CLR is a more proper algorithm to
655 choose for gap-filling the drivers due to its simplicity and less calculation requirement).

656 The FBP was a unique algorithm used in this research, as it did not use any independent
657 variables to estimate the values of drivers and fluxes. The FBP performance was the least satisfactory
658 of all the algorithms. Therefore, FBP cannot be considered as a reliable alternative for current
659 algorithms to fill the gaps, especially longer ones.

660 Given that some of the environmental drivers that affect F_c are different during the day versus
661 night, separating the diurnal and nocturnal datasets to train the algorithms could improve the
662 outcome. Mainly because of the u^* threshold filtering and other problems associated with the
663 nocturnal period, the portion of diurnal data is generally, by far, outweighs the nocturnal data portion,
664 which potentially leads to a bias in the algorithm. The same challenge is associated with soil moisture
665 estimation, as the behaviour of the system's behaviour on sunny days is utterly different from during
666 the rainy periods. Moreover, the system memory and the antecedent condition are undeniable features
667 associated with soil moisture (Ogle et al., 2015). Therefore, using models that can address these
668 considerations are more likely to improve the estimations.

669 Finally, it is noteworthy that some of the flux drivers used in this study as input features for
670 the gap-filling algorithms are not commonly used or might not globally be available. However,
671 considering that similar relative performance has been achieved in other researches for which
672 different sets of input features had been used (Kim et al., 2020), the relative performance of the
673 algorithms reviewed in this research should generally provide similar relative performance while
674 using different input features.

675 5. Conclusions

676 Eight different gap-filling algorithms for estimating 16 meteorological drivers as well as nine
677 algorithms for the three key ecosystem turbulent fluxes (sensible heat flux (F_h), latent heat flux (F_e),
678 and net carbon flux (F_c)) were investigated, and their performance evaluated based on the datasets of
679 five towers in Australia. Overall, three ML algorithms, XGB, RF and ANNs, performed nearly equally
680 well and significantly better than their linear rivals (the CLR, PD, and ELN) in estimating the flux
681 values. However, the linear algorithms performed almost equally well as the ML algorithms in
682 assessing the meteorological drivers. Amongst these nine algorithms, the RF and XGB showed the
683 highest level of robustness and reliability in estimating the F_c , F_e , and F_h . The PD was expected to
684 perform better than the linear methods, and it was hoped to compete with the ML algorithms in
685 estimating the fluxes, but it failed to do so. The SVR was the only ML algorithm that did not perform
686 at the same level as the rest ML algorithms that we suspect were due to over-fitting issues, while the
687 MDS performed somewhere in between. Considering the outcomes of previous research undertaken
688 in the OzFlux Network (e.g. (Cleverly et al., 2013; Isaac et al., 2017)), none of the ML algorithms used

689 in this research was proven to provide substantially better flux estimations compared with the
690 standard method (ANNs). Nonetheless, amongst the algorithms tested in this research, the RF showed
691 potential capabilities as an alternative due to its more consistent performance regarding the long gaps.
692 Finally, we recommend suggestions below to improve the results for similar prospective researchers,
693 as well as the QC and gap-filling procedure for flux networks:

694 1) Since the RF was more consistent than its competitors, including the ANNs, we suggest it is a good
695 idea to use RF alongside the commonly used algorithms in challenging scenarios, such as long gaps,
696 to figure out whether this superiority can be generalised.

697 2) It appears that even after three levels of quality control process done by the flux processing software
698 (e.g. PyFluxPro), the data is still quite noisy. These noisy data are an essential source of both
699 uncertainty and inaccuracy of the outcome, regardless of the algorithm used to gap-fill the data. As a
700 result, another level of quality control methods, such as Wavelets or Matrix Factorisation, in addition
701 to the current classical ones used by the PyFluxPro and other similar platforms, can probably improve
702 the data quality and thereby improve the final imputation results.

703 3) For future researchers, using recurrent neural networks (RNNs) instead of feedforward neural
704 networks (FFNN) could improve the estimations. That is likely because RNNs help the model to
705 consider temporal dynamic behaviour of time series, as unlike FFNN, wherein the activations flow
706 only from the input layer to the output layer, RNNs also have neuron connections pointing backwards
707 (Géron, 2019). There is a demand for an algorithm capable of considering time has been mentioned in
708 previous research as one of the reasons why testing the new algorithms is needed (Richardson and
709 Hollinger, 2007).

710 4) Developing ensemble models using algorithms with different weaknesses and strengths may also
711 enhance the results where a single algorithm shows performance deficiency.

712

713 6. Data availability

714 The data were used in this research are available through the following sources: The L3 and L4
715 data are accessible from the OzFlux data portal (<http://data.ozflux.org.au/portal>). Current ACCESS-R
716 and data are available from the BoM OPeNDAP server (<https://www.opendap.org/>). Likewise, the
717 data coming from the BoM AWS are accessible from (<http://www.bom.gov.au/climate/data>). Lastly,
718 the BIOS2 data are accessible from the ECMWF datasets portal
719 (<https://www.ecmwf.int/en/forecasts/datasets>). All data used in this research are available in this
720 repository address: ([https://research-repository.uwa.edu.au/en/datasets/a-comparison-of-gap-filling-
721 algorithms-for-eddy-covariance-fluxes](https://research-repository.uwa.edu.au/en/datasets/a-comparison-of-gap-filling-algorithms-for-eddy-covariance-fluxes)); DOI: [10.26182/5f292ee80a0c0](https://doi.org/10.26182/5f292ee80a0c0).

722

723 *Author contributions.* The ideas for this study originated in discussions with A. Mahabbati, J. Beringer,
724 and M. Leopold. A. Mahabbati carried out the analysis, supported by I. McHugh and P. Isaac. The
725 paper was prepared with contributions from all authors.

726

727 *Competing interests.* The authors declare that they have no conflict of interest.

728

729 *Acknowledgements.* The authors would like to acknowledge the Terrestrial Ecosystems Research
730 Network (TERN) (www.tern.gov.au) and the OzFlux Network as a part of TERN for supporting the
731 grants and providing the required data, respectively. A. Mahabbati also personally thanks Prajwal
732 Kalfe, Caroline Johnson and Cacilia Ewenz for their support regarding Python programming, English
733 academic writing and PyFluxPro technical issues.
